 - Signal Model
- 2 Our Proposed Method
 - Belief Propagation-Based Inference
 - Simulation Studies
- 3 Conclusions

Fundamentals of the Dynamic CS Problem

The *dynamic CS* problem concerns recovering a temporal sequence of signals, $\{\mathbf{x}^{(t)}\}_{t=0}^T$, from an undersampled sequence of measurements, $\{\mathbf{y}^{(t)}\}_{t=0}^T$, where $\mathbf{y}^{(t)} = \mathbf{A}^{(t)}\mathbf{x}^{(t)} + \mathbf{e}^{(t)}$.

Assumed time-varying signal properties

- 1 The time-varying signal is sparse (or compressible) in an appropriately chosen basis.
- 2 The support set of the signal changes slowly over time.
- 3 The amplitudes of the non-zero coefficients evolve smoothly in time.

Example: Angiography Sequence

Image source: Koninklijke Philips Electronics N.V.

- Our goals
 - Unified approach to filtering and smoothing
 - Algorithm complexity that is linear in problem dimensions
 - Principled framework: Switching linear dynamical systems (SLDSs), Gaussian sum filtering/smoothing

A Model of Sparse Time-Evolving Signals

We write: $x_n^{(t)} = s_n^{(t)} \cdot \theta_n^{(t)}$ for $s_n^{(t)} \in \{0,1\}$ and $\theta_n^{(t)} \sim \mathcal{CN}(0, \sigma^2)$.

Support Set Evolution

Treat $\{s_n^{(t)}\}_{t=0}^T$ as a Markov chain characterized by two transition probabilities:

$$p_{01} \triangleq \Pr\{s_n^{(t)} = 0 | s_n^{(t-1)} = 1\} \text{ and}$$
$$p_{10} \triangleq \Pr\{s_n^{(t)} = 1 | s_n^{(t-1)} = 0\}.$$

Amplitude Evolution

Treat $\{\theta_n^{(t)}\}_{t=0}^T$ as a Gauss-Markov process:

$\theta_n^{(t)} = (1 - \alpha)\theta_n^{(t-1)} + \alpha w_n^{(t)}$, where $w_n^{(t)} \sim \mathcal{CN}(0, \rho)$, and α controls the correlation in the random process.

Leads to Bernoulli-Gaussian distribution for $x_n^{(t)}$:

$$p(x_n^{(t)}) = (1 - \pi_n^{(t)})\delta(x_n^{(t)}) + \pi_n^{(t)}\mathcal{CN}(x_n^{(t)}; 0, \sigma^2)$$

A Model of Sparse Time-Evolving Signals

Estimating the Time-Varying Signal

- Signal model is stochastic, thus our estimation procedure will be statistical in nature
- Belief propagation (BP) technique:
 - Suitable for performing inference when the posterior joint distribution factors into a product of marginal distributions that depend on small subsets of variables. Conveniently visualized via a *factor graph*.
 - Message passing algorithm in which messages traversing the factor graph are pdfs and pmfs
 - Messages described parametrically by just a few scalar variables, e.g. means and variances
 - Fast (if simplified), but approximate on loopy graphs

 - Fast (if simplified), but approximate on loopy graphs

BP Implementation Highlights

- In general, CS measurement matrices, $\mathbf{A}^{(t)}$, are dense. Implementing standard BP would thus require evaluating multi-dimensional integrals that grow exponentially in number as problem dimensions grow
- Simplification: Approximate message passing (AMP) approach, [Donoho, Maleki, Montanari '09]
 - AMP has been shown to achieve asymptotic optimality, providing exact posteriors as $M, N \rightarrow \infty$ [Bayati, Montanari '10]
 - Complexity of iterative thresholding algorithms
 - Requires only $\mathcal{O}(MN)$ computations per timestep in the form of matrix-vector products

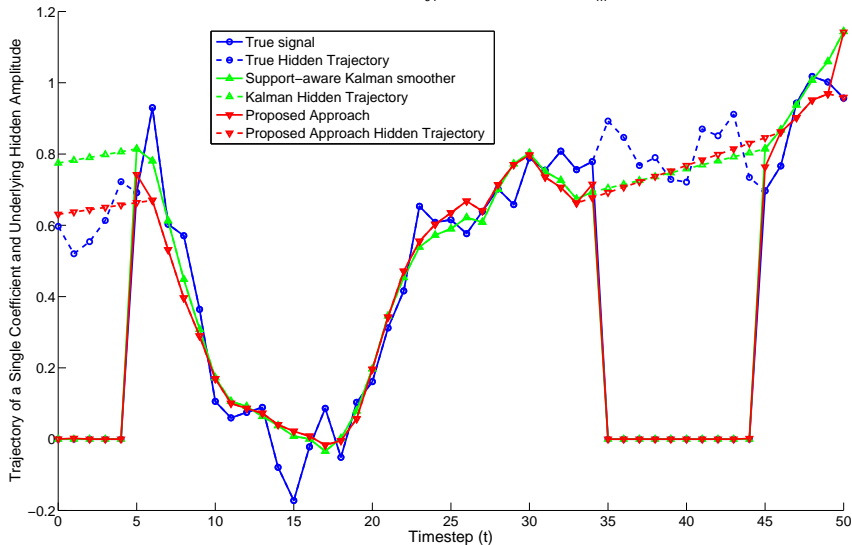

Sample Trajectory, Single Coefficient

$N = 256$, $M = 32$, $T = 50$, $p_{01} = 0.05$, $\alpha = 0.01$, $\text{SNR}_m = 15\text{dB}$

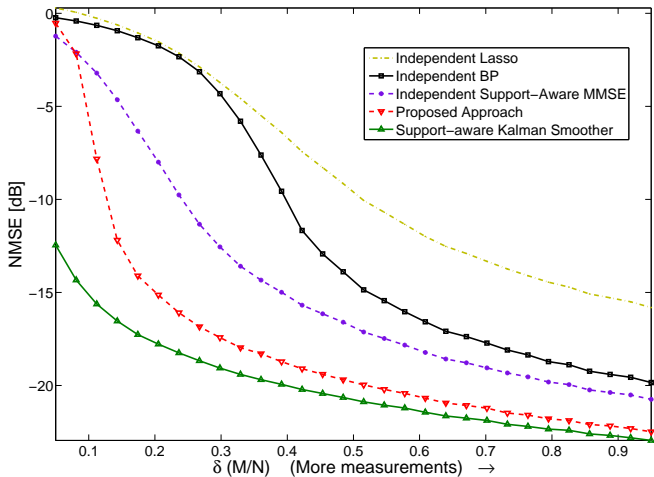

Sample Trajectory, Hidden Variables

$N = 256$, $M = 32$, $T = 50$, $p_{01} = 0.05$, $\alpha = 0.01$, $\text{SNR}_m = 15\text{dB}$

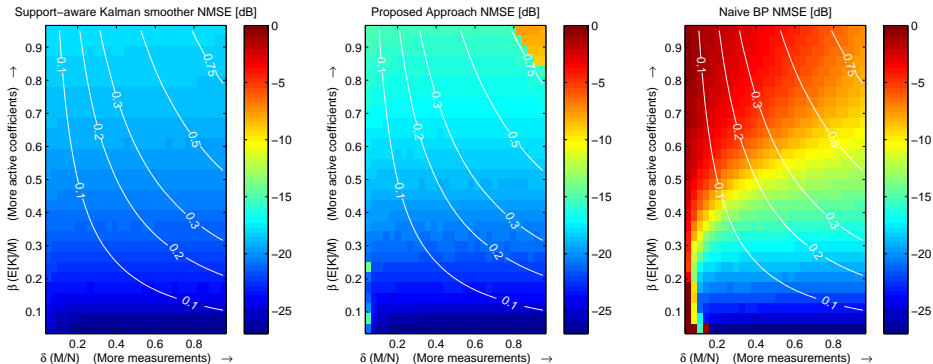

MSE Performance vs. # of Measurements

NMSE vs. # of Measurements | $N = 512$, $T = 25$, $\lambda = 0.2$, $p_{01} = 0.05$, $\alpha = 0.01$, $\text{SNR}_m = 15\text{dB}$, $N_{\text{trials}} = 100$

Sparsity-Undersampling Plane: MSE Performance

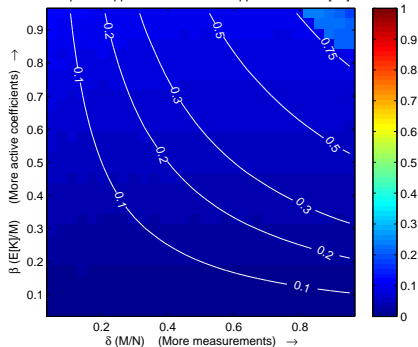

$N = 512, p_{01} = 0.05, \alpha = 0.01, T = 25, \text{SNR} = 15 \text{ dB}$

Sparsity-Undersampling Plane: Support Estimation Performance

$$\text{NSER} \triangleq \frac{\# \text{ of Errors in Support Estimate}}{\# \text{ of True Non-Zero Coefficients}}$$

Proposed Approach Normalized Support Error Rate [dB]

Naive BP Normalized Support Error Rate [dB]

Summary

- Presented a novel signal model for describing sparse, time-varying signals
- Described a belief propagation-based inference algorithm that implements both tracking and smoothing
 - AMP approach enables rapid estimation ($\mathcal{O}(MN)$ computations per timestep/pass)
- Compared performance against timestep-independent CS solvers and a support-aware Kalman smoother
 - Proposed approach drastically outperforms timestep-independent methods, and approaches the support-aware Kalman smoother in performance
