## Plug-and-Play (PnP) Image Recovery

- Goal: Recover  $N$ -pixel image  $x_0$  from  $M \ll N$  noisy linear measurements
 
$$y = Ax_0 + w, \text{ with } \begin{cases} x_0 : \text{true image} \\ A : \text{linear measurement operator} \\ w : \text{AWGN with precision } \gamma_w. \end{cases}$$
- Although deep nets can be trained to predict  $x_0$  from  $y$ , they
  - require a huge number of  $(x_0, y)$  pairs for training
  - may not generalize well to a different  $A$  operators
- Plug-and-play (PnP) algorithms iteratively call a deep-net image denoiser, which can be trained ...
  - from very few images, using patches
  - independently of  $A$ , facilitating generalization to any  $A$
- Challenge: In PnP, the denoiser input-error statistics are iteration-dependent and difficult to characterize. For example, they are generally non-white and non-Gaussian
- Thus, it's not clear how to train the denoiser for optimal performance in PnP!
  - Typically the denoiser is trained with AWGN
  - Gilton et al. recently proposed to train the denoiser at the PnP equilibrium point, but it's  $A$ -dependent and thus may not generalize

## Approximate Message Passing (AMP) Algorithms

- AMP is a family of PnP algorithms that have remarkable properties for large random  $A$ :
  - The denoiser input-error is white and Gaussian with predictable variance
  - When used with an MMSE denoiser, AMP algs converge to the MMSE estimate of  $x_0$  from  $y$
- Challenge: In most image recovery problems,  $A$  does not satisfy AMP's randomness assumptions

## AMP for Fourier-Structured Matrix $A = MF$

- Idea: Recover the wavelet coefficients  $c_0$ , not pixels  $x_0$ 
  - Why? The resulting model becomes  $y = Bc_0 + w$ , where the masked Fourier-wavelet  $B = MF\Psi^T$  is approximately block-diagonal with sufficiently randomizing blocks
- With appropriate algorithm design, the denoiser input-error will be white and Gaussian in each wavelet subband
- Prior work includes Whitened VAMP [PS et al. '17], Variable-Density (VD)-AMP [Millard et al. '20], based on wavelet thresholding, & Denoising-VD-AMP [Metzler et al. '21]
- Note: These algorithms provide well-characterized errors, but a non-standard denoiser is required to exploit them!

## Proposed Algorithm: Denoising GEC (D-GEC)

Our approach builds on the Generalized Expectation Consistent (GEC) algorithm from Fletcher et al. '16:

```

require:  $f_1(\cdot)$ ,  $f_2(\cdot)$ , and  $\text{gdiag}(\cdot)$ 
initialize:  $r_1, \gamma_1$ 
for  $t = 0, 1, 2, \dots$ 
     $\hat{x}_1 \leftarrow f_1(r_1, \gamma_1)$  linear estimation
     $\eta_1 \leftarrow \text{Diag}(\text{gdiag}(\nabla f_1(r_1, \gamma_1)))^{-1} \gamma_1$ 
     $\gamma_2 \leftarrow \eta_1 - \gamma_1$ 
     $r_2 \leftarrow \text{Diag}(\gamma_2)^{-1} (\text{Diag}(\eta_1) \hat{x}_1 - \text{Diag}(\gamma_1) r_1)$  Onsager

     $\hat{x}_2 \leftarrow f_2(r_2, \gamma_2)$  denoising
     $\eta_2 \leftarrow \text{Diag}(\text{gdiag}(\nabla f_2(r_2, \gamma_2)))^{-1} \gamma_2$ 
     $\gamma_1 \leftarrow \eta_2 - \gamma_2$ 
     $r_1 \leftarrow \text{Diag}(\gamma_1)^{-1} (\text{Diag}(\eta_2) \hat{x}_2 - \text{Diag}(\gamma_2) r_2)$  Onsager
    
```

- GEC is essentially Peaceman-Rachford ADMM with adaptive vector-valued stepsizes  $\gamma_1$  and  $\gamma_2$
- The GEC linear estimation stage is preconditioned LS:
 
$$f_1(r, \gamma) = (\gamma_w B^H B + \text{Diag}(\gamma))^{-1} (\gamma_w B^H y + \text{Diag}(\gamma) r)$$
 which can be implemented using the conjugate gradient method
- $\nabla f_i$  denotes the Jacobian, and  $\text{gdiag}(\cdot)$  averages its diagonal across different wavelet subbands. D-GEC approximates the Jacobian using a Monte-Carlo approach [Ramani et al. '08]

## New Update-Proposed Denoiser: corr+corr

- In the wavelet domain, the denoiser input-error is white and Gaussian in each subband, but with subband-dependent inverse-variances  $\gamma$  that change with the iterations
  - Thus, in the pixel-domain, the error is correlated Gaussian with known covariance matrix  $\Psi \text{Diag}(\gamma)^{-1} \Psi^T$
  - How should we inform the denoiser about  $(\Psi, \gamma)$ ?
- We propose to add an extra input channel to an arbitrary denoiser (e.g., DnCNN) and feed it with an independent realization of  $\mathcal{N}(0, \Psi \text{Diag}(\gamma)^{-1} \Psi^T)$ 
  - The denoiser learns to extract the statistics  $(\Psi, \gamma)$  from  $e$  and use them productively for denoising
  - We call it "corr+corr"

- Example PSNRs for depth-1 2D wavelet transform:

$\sqrt{\gamma}^{-1}$	white DnCNN	corr+corr DnCNN	genie DnCNN
[48,47,6,19]	25.54	32.32	32.79
[10,40,23,14]	33.08	35.84	36.47
[13,7,8,10]	36.93	37.53	37.90
[10,10,10,10]	38.03	37.92	38.21
uniform [0-50,0-50,0-50,0-50]	32.18	35.34	—

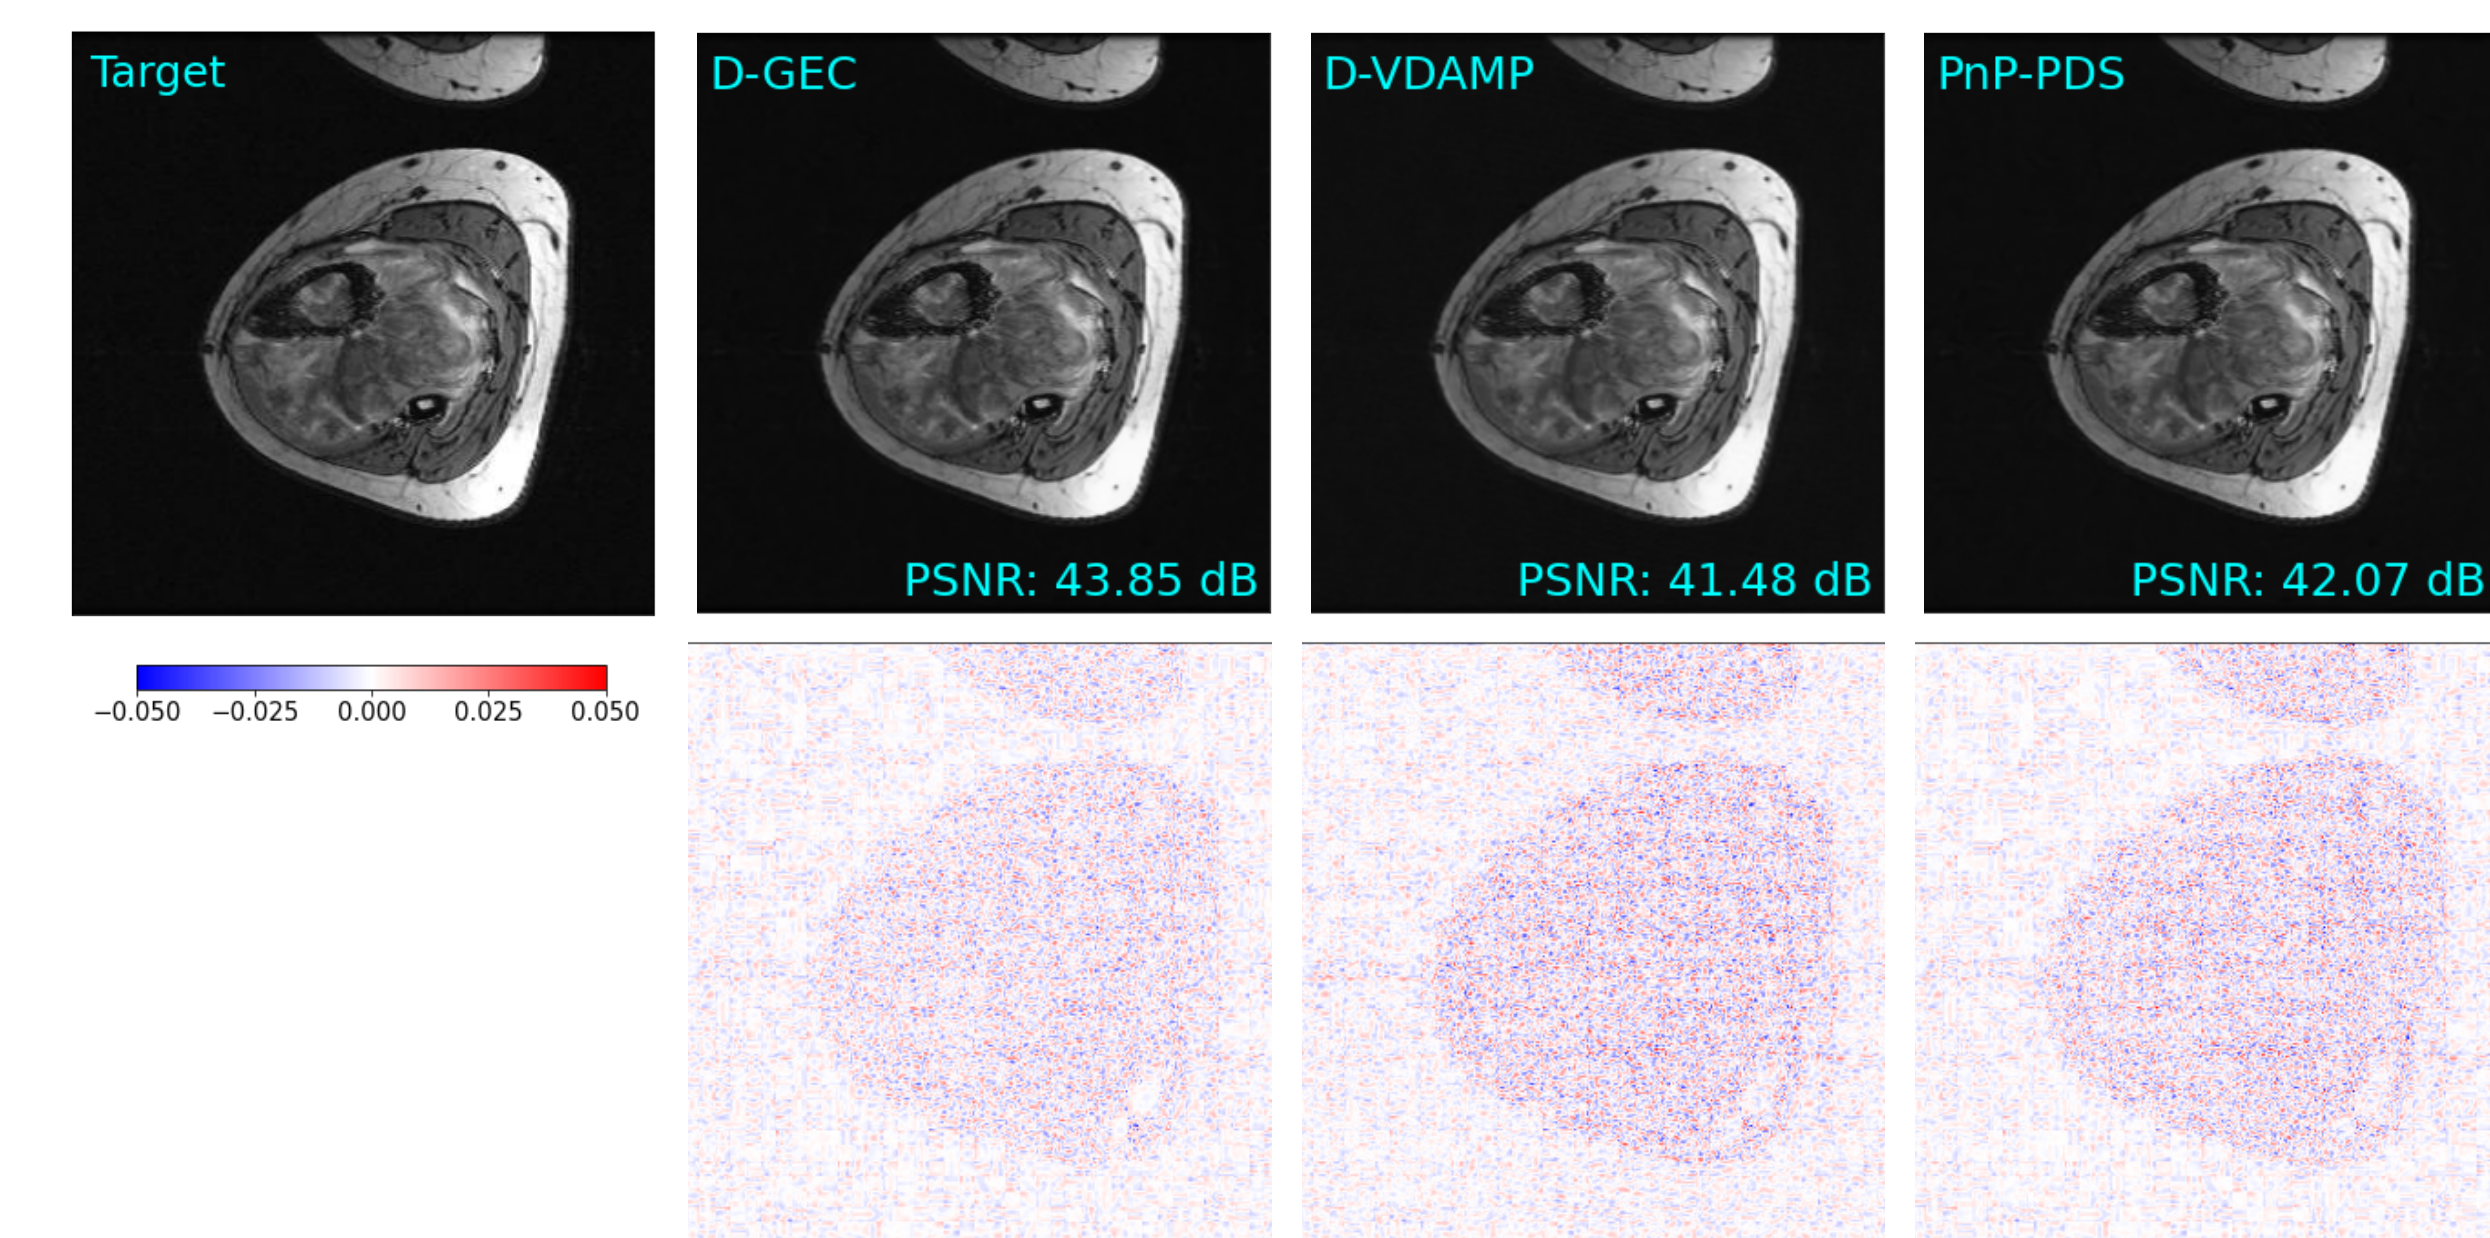

White trained unif [0-50] and & corr+corr unif [0-50,0-50,0-50,0-50]

## New Results: MRI Image Recovery Experiments

- We consider single coil measurements  $y = MFx_0 + w$
- Experimental setup:
  - $M$  is a variable density mask
  - $w$  is AWGN giving pre-mask SNR = 40 dB
  - $\Psi$  is 2D Haar wavelet transform with  $D = 4$  levels  $\Rightarrow$  13 subbands
  - PnP-PDS uses bias-free white-noise DnCNN and careful tuning
  - D-VDAMP uses the modified DnCNN denoiser from that paper
  - D-GEC uses bias-free corr+corr DnCNN
  - training data: 62 000 48x48 patches from 70 training images of the Stanford 2D FSE dataset
  - 5 copies DnCNN-c+c were trained using sub-band noise SDs uniformly distributed in the ranges 0-10, 10-20, 20-50, 50-120, and 120-500
- Avg performance on 10 Stanford 2D FSE 352x352 test images:

$C = 1$ coil method	$M/N = 1/4$ PSNR	$M/N = 1/4$ SSIM	$M/N = 1/8$ PSNR	$M/N = 1/8$ SSIM
PnP-PDS	45.97	0.978	41.28	0.957
D-VDAMP	44.61	0.974	38.43	0.901
D-GEC	47.64	0.982	42.42	0.959

- Example single-coil recoveries and error maps at  $M/N = 1/4$ :

- Standard deviation of D-GEC denoiser-input error vs iteration:

- Example wavelet-error QQ plots at iteration 10:
